**DEATHS
FROM EXPOSURE TO
EXCESSIVE NATURAL HEAT
OCCURRING IN ARIZONA,
1992-2002**

by
Christopher K. Mrela, Ph.D.,
Assistant Registrar of Vital Statistics

MARCH 2004

Acknowledgments

Special gratitude is expressed to Trentham Coe, who developed the GIS map for this report, and to Wes Kortuem for his assistance with this task. Trentham also formatted the manuscript for the Web.

Particular thanks are extended to Brian Bender who verified with the Pima County Office of the Medical Examiner the 2002 cases of heat-related deaths in La Paz, Pima, Pinal and Santa Cruz counties.

DEATHS FROM EXPOSURE TO EXCESSIVE NATURAL HEAT OCCURRING IN ARIZONA, 1992-2002

Purpose

The purpose of this report is to provide information concerning deaths from exposure to heat due to weather conditions occurring in Arizona. Unlike our other reports, designed to monitor health status of the residents of Arizona, this publication is focused on mortality occurring in the State to both residents and non-residents. The data for 2002 (the latest year with complete information) are placed in a temporal context by comparison with the data for the preceding ten years.

The report *Deaths from exposure to excessive natural heat occurring in Arizona, 1992 – 2002* was prepared as a supplement to injury mortality statistics for Arizona residents. These statistics are updated annually through a series of publications, including the *Arizona Health Status and Vital Statistics* (<http://www.hs.state.az.us/plan/report/ahs/ahs2002/pdf/130.pdf>) and *Injury Mortality Among Arizona Residents* (unintentional injury section: <http://www.hs.state.az.us/plan/report/im/index.htm>).

Methods and Sources

Data on the number and characteristics of deaths from heat due to weather conditions were obtained from the mortality database containing information from the death certificates filed with the Arizona Department of Health Services.

The *International Classification of Diseases* (ICD) permits the classification of environmental events and circumstances as the external cause of injury death. Beginning with the 2000 data year in Arizona (1999 nationally) the Tenth Revision of the International Classification of Diseases (ICD-10) has replaced the Ninth Revision (ICD-9), which was in effect since 1979. Exposure to excessive natural heat as the underlying cause of death is identified by a three-character category X30 in the Tenth Revision and corresponding to it code E900.0 in the Ninth Revision. In this report, the deaths from exposure to heat due to weather conditions are classified by ICD-9 for 1992-1999 and by ICD-10 for 2000-2002.

In addition to death certificates where exposure to excessive natural heat was indicated as the underlying cause of death, heatstroke or sunstroke may be reported on death certificates as contributing factors that had a bearing on the death, but were not its underlying cause.

For example, heatstroke and sunstroke were mentioned in 2002 on death certificates where brain cancer (D43.2), atherosclerotic cardiovascular disease (I25.0), dilated cardiomyopathy (I42.0), urinary tract infection (N39.0), exposure to other and unspecified forces of nature (X39), accidental overdose of narcotics (X42) and other event of undetermined intent (Y33) were reported as the underlying cause of death. Those heat-related deaths are beyond the scope of this report.

Summary of Findings

From 1992 to 2002, 570 deaths from exposure to heat due to weather conditions occurred in Arizona. The residents of the State accounted for a majority of these deaths (315, or 55.3 percent). On average, 29 Arizona residents died every year from a heatstroke or sunstroke in the eleven-year period 1992-2002.

Visitors to Arizona from other U.S. states or Canada experienced 41 deaths from exposure to heat due to weather conditions during the 1992-2002 period.

The 214 deaths from exposure to excessive natural heat among the illegal immigrants crossing the Arizona's border with Mexico accounted for 37.5 percent of all deaths due to this cause that occurred in the State during the 1992-2002 period. The vast majority (196, or 91.6 percent) of these deaths occurred in the five years from 1998 to 2002.

Unprecedented increase in the number of deaths from natural heat among migrants (from no fatalities in 1992, to 13 deaths reported in 1998 and 80 deaths in 2002) was likely to be linked to an increase in illegal immigrant traffic across Arizona's part of the U.S. – Mexico border.

Ironically, it may have been to some extent the result of a rather successful crackdown on illegal immigrants in Texas, New Mexico and California. By 1998, there was a substantial decline in the number of arrests in the traditional illegal immigration corridors of these three states, while the Tucson sector of Arizona was to become **the busiest illegal-crossing corridor along the Southwest border**. Prior to 1998, the average annual mortality from exposure to heat among the illegal immigrants crossing the State's southern border did not exceed three (3) deaths/year.

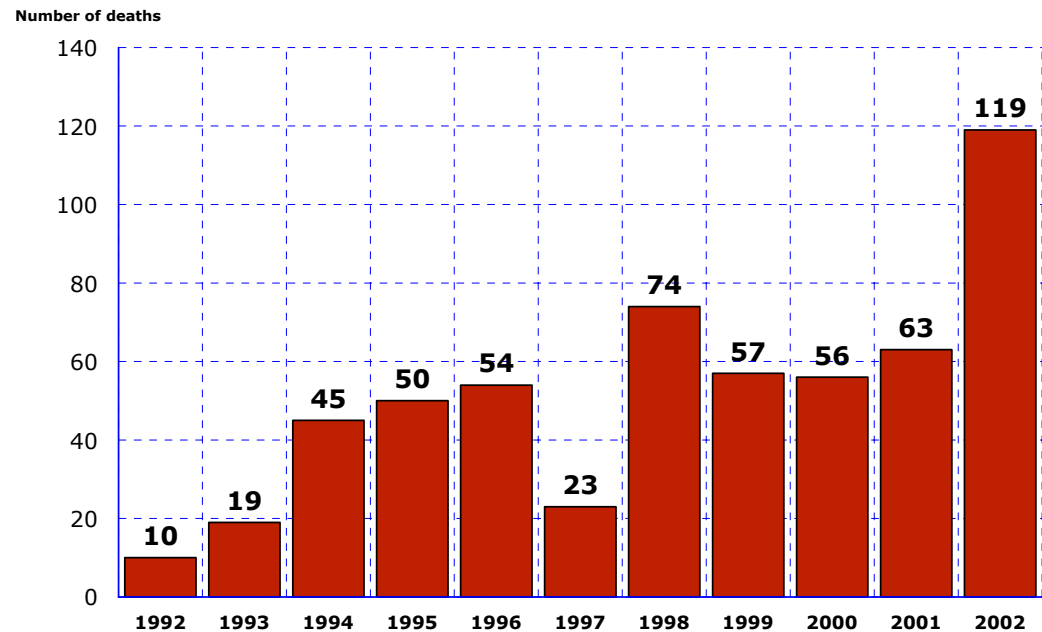

Figure 1

**DEATHS FROM EXPOSURE TO EXCESSIVE NATURAL HEAT*
OCCURRING IN ARIZONA BY YEAR, 1992-2002**

In the eleven-year period from 1992 to 2002, 570 deaths from exposure to excessive natural heat occurred in Arizona.

The number of deaths from exposure to excessive natural heat has shown a wide variation from year to year (low = 10 deaths in 1992, high = 119 deaths in 2002). On average, 52 people died every year from a heatstroke or sunstroke in the eleven-year period from 1992 to 2002. The number of 119 deaths from exposure to heat due to weather conditions in 2002 accounted for one-fifth (119/570 or 20.9 percent) of these deaths (**Figure 1, Table 1**).

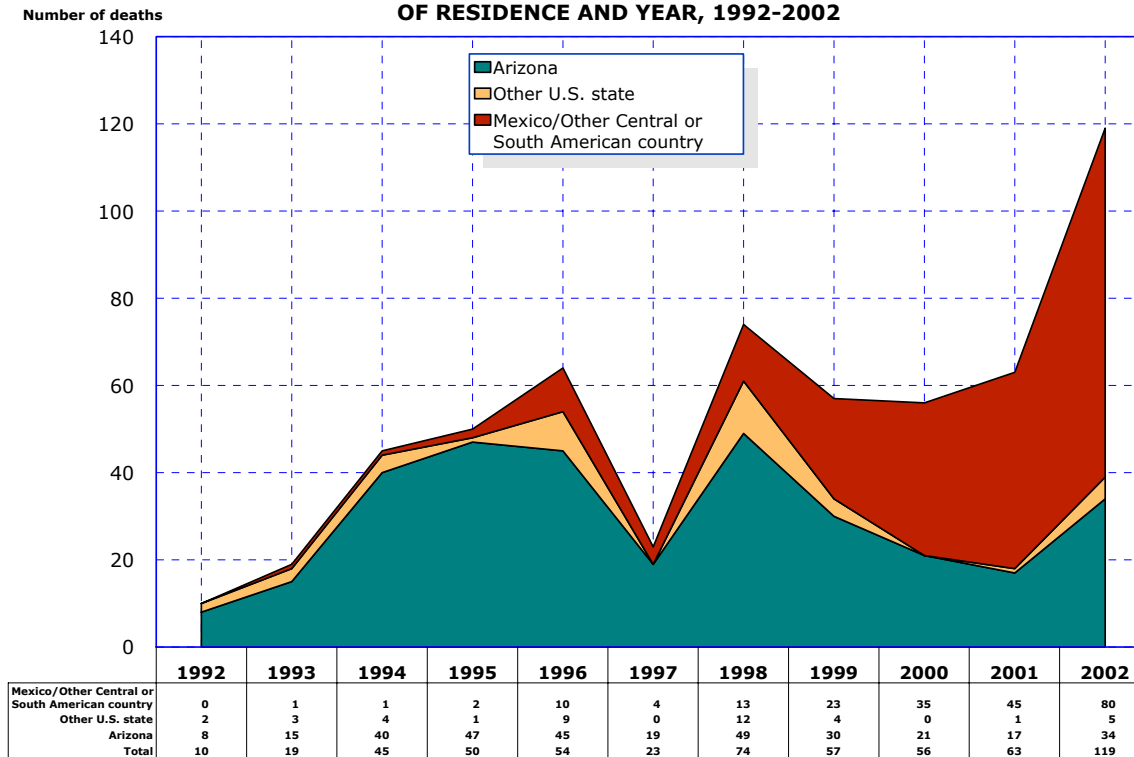

Approximately seven out of every ten deaths from exposure to excessive natural heat in 1992-2002 were males (412/570 or 72.3 percent, **Table 1**).

*The underlying cause of death was classified as E900.0 by ICD-9 (1992-1999) or as X30 by ICD-10 (beginning in 2000). Included are deaths occurring in Arizona from excessive heat due to weather conditions as the cause of heatstroke or sunstroke among both residents of Arizona and non-residents. Excluded are deaths due to excessive heat of man-made origin.

Figure 2

DEATHS FROM EXPOSURE TO EXCESSIVE NATURAL HEAT*
OCCURRING IN ARIZONA BY STATE OR COUNTRY
OF RESIDENCE AND YEAR, 1992-2002

*The underlying cause of death was classified as E900.0 by ICD-9 (1992-1999) or as X30 by ICD-10 (beginning in 2000). Included are deaths occurring in Arizona from excessive heat due to weather conditions as the cause of heatstroke or sunstroke among both residents of Arizona and non-residents. Excluded are deaths due to excessive heat of man-made origin.

From 1992 to 2002, the residents of the State accounted for a majority of deaths from exposure to heat due to weather conditions (315/570, or 55.3 percent).

Visitors to Arizona from other U.S. states or Canada experienced 41 deaths from exposure to heat due to weather conditions during the 1992-2002 period.

The 214 deaths from exposure to excessive natural heat among the illegal immigrants crossing the Arizona's border with Mexico accounted for 37.5 percent of all deaths due to this cause that occurred in the State during the 1992-2002 period. The vast majority (196, or 91.6 percent) of these deaths occurred in the five years from 1998 to 2002. There was no climate change, which could explain this unprecedented increase in the number of Arizona deaths from natural heat among illegal immigrants (from no fatalities in 1992, to 13 deaths reported in 1998 and 80 deaths in 2002). Rather, the increase in mortality was likely to be linked to an increase in illegal immigrant traffic across Arizona's part of the U.S. - Mexico border. It is not unreasonable to assume, that it may have been to some extent the result of a rather successful crackdown on illegal immigrants in Texas, New Mexico and California. By 1998, the success¹ of several border operations (Operation Gatekeeper in San Diego, Operation Hold the Line in El Paso, Operation Rio Grande in McAllen) effected a substantial decline in the number of arrests in the traditional illegal immigration corridors of these three states, while the Tucson sector of Arizona's border was to become "the busiest illegal-crossing corridor along the Southwest border"². Prior to 1998, the average annual mortality from exposure to heat among the illegal immigrants crossing the State's southern border did not exceed three (3) deaths/year.

Figure 3

**DEATHS FROM EXPOSURE TO EXCESSIVE NATURAL HEAT*
OCCURRING IN ARIZONA BY MONTH IN THE
ELEVEN-YEAR PERIOD, 1992-2002**

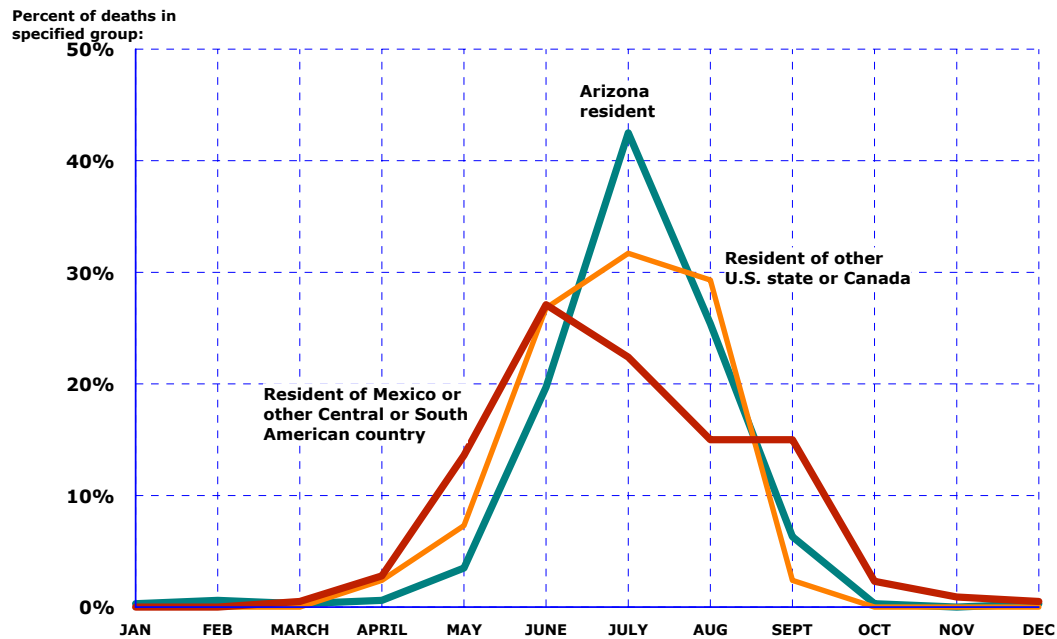

Not surprisingly, in Arizona (1992-2002) most deaths from excessive natural heat occurred during summer and late spring (**Figure 3, Table 2, Table 3**), with the highest number of deaths occurring during the month of July (195), followed by June (131), then August (124), September (53) and May (43). In 1992-2002, ninety-six percent of all deaths from heat to weather conditions occurred during the five months from May through September.

*The underlying cause of death was classified as E900.0 by ICD-9 (1992-1999) or as X30 by ICD-10 (beginning in 2000). Included are deaths occurring in Arizona from excessive heat due to weather conditions as the cause of heatstroke or sunstroke among both residents of Arizona and non-residents. Excluded are deaths due to excessive heat of man-made origin.

Figure 4

PERCENT DISTRIBUTION OF DEATHS FROM EXPOSURE TO EXCESSIVE NATURAL HEAT* OCCURRING IN ARIZONA BY MONTH AND RESIDENCE STATUS IN THE ELEVEN-YEAR PERIOD, 1992-2002

Among both the residents of Arizona and visitors from other states, most deaths from excessive natural heat occurred during the month of July (**Figure 4, Table 2**). Among migrants to Arizona from 1992 through 2002, the highest number of deaths occurred during the month of June. The difference in the seasonal pattern of mortality may mean that fewer migrants attempted to cross the border in July and August, the two summer months with the highest temperatures.

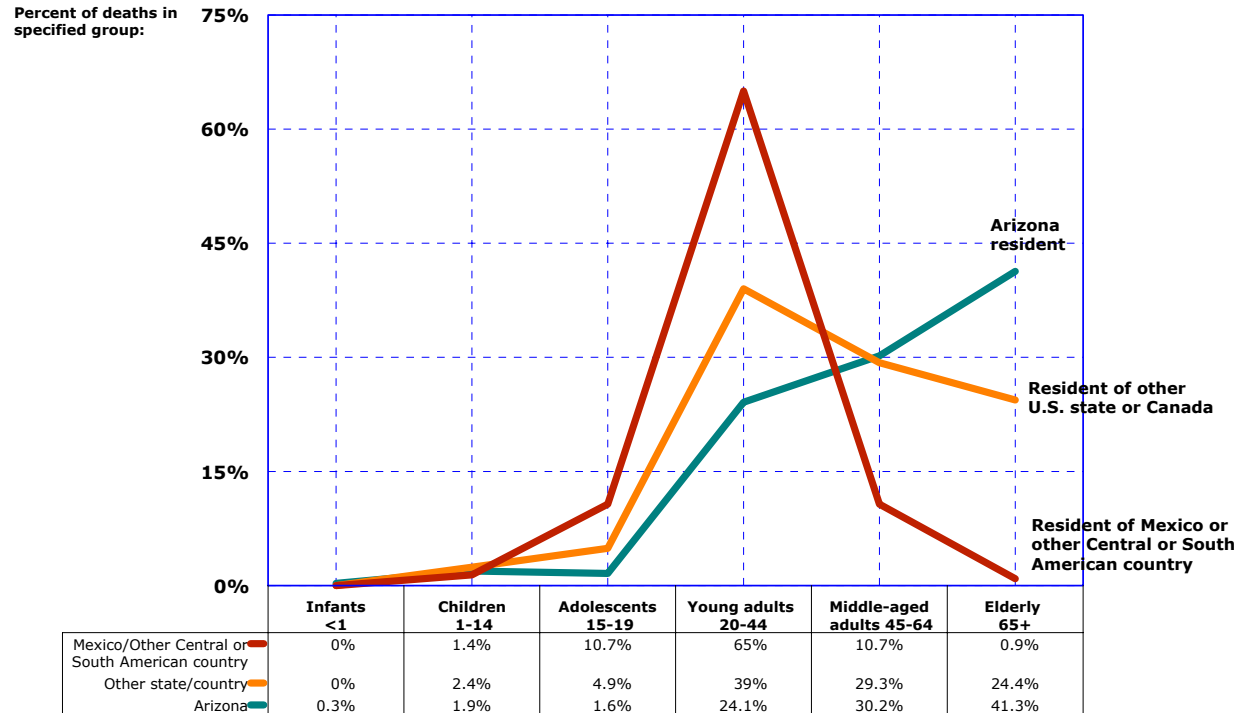

*The underlying cause of death was classified as E900.0 by ICD-9 (1992-1999) or as X30 by ICD-10 (beginning in 2000).

Figure 5

PERCENT DISTRIBUTION OF DEATHS FROM EXPOSURE TO EXCESSIVE NATURAL HEAT* OCCURRING IN ARIZONA BY AGE GROUP AND RESIDENCE STATUS IN THE ELEVEN-YEAR PERIOD, 1992-2002

In 1992-2002, deaths from exposure to excessive natural heat among migrants to Arizona occurred at younger ages compared to deaths from natural heat among the State's residents (**Figure 5**). Historically, older adults 65 years or older have been at the highest risk of heatstroke or sunstroke among the age groups of Arizona residents. Less than one percent of all deaths from natural heat among migrants were 65 years and older, while 41.3 percent of fatalities due to exposure to heat among Arizona residents were this old. In fact, deaths from excessive heat ranked fifth among the leading causes of accidental death for Arizona elderly 65 years or older in 1992-2002 (http://www.hs.state.az.us/plan/report/im/im/im02/2/xls/t2_14.xls). See also Chapter 2 of the report on **Injury Mortality Among Arizona Residents, 1990-2002** available at <http://www.hs.state.az.us/plan/report/im/im/im01/im00/imc2.pdf>.

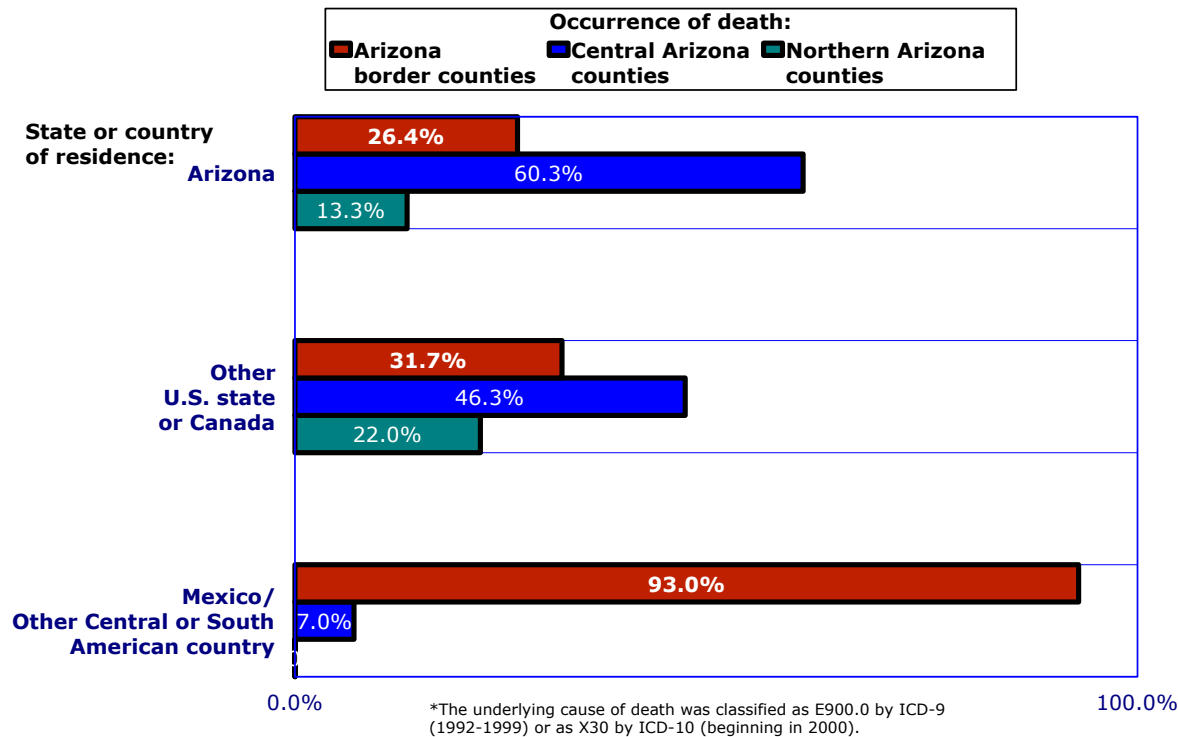

Not surprisingly, young adults 20-44 years old accounted during 1992-2002 for 65 percent of deaths from exposure to excessive natural heat among the migrants from Mexico and other Central/South American countries.

*The underlying cause of death was classified as E900.0 by ICD-9 (1992-1999) or as X30 by ICD-10 (beginning in 2000).
 Note: the age was unknown for 24 (11.2 percent) of the illegal immigrants from Mexico and other Central or South American countries.

Figure 6

PERCENT DISTRIBUTION OF DEATHS FROM EXPOSURE TO EXCESSIVE NATURAL HEAT* BY RESIDENCE STATUS AND AREA OF OCCURRENCE IN ARIZONA IN THE ELEVEN-YEAR PERIOD, 1992-2002

The four counties along the southern border of Arizona (Cochise, Pima, Santa Cruz, and Yuma) accounted for 93 percent of deaths from excessive heat due to weather conditions among the illegal immigrants (**Figure 6, Table 3**). In contrast, the centrally situated Maricopa County accounted for the majority of deaths from heat due to weather conditions among both the residents of Arizona and visitors from other States.

Beginning with the 2001 data year, information about the specific geographic location of fatal injury was included in the mortality database. In 2001-2002, among the 125 deaths of migrants from exposure to excessive natural heat, 99 occurred in Pima County, most of them in the remote desert areas of the Tohono O’odham Indian reservation (**Figure 7, next page**).

Case summaries of the eighty deaths of migrants to Arizona in 2002, including the geographic location of injury, the city of deaths, the immediate cause of death, age and gender of the deceased, are shown in **Table 4**.

TABLE 3 (CONTINUED)
CHARACTERISTICS OF ARIZONA DEATHS FROM EXPOSURE TO EXCESSIVE NATURAL HEAT BY REGION,
ELEVEN-YEAR SUMMARY FOR 1992-2002

		Total	Border counties	Central Arizona counties	Northern Arizona counties
Month of death	JAN	1	0	0	1
	FEB	2	1	0	1
	MARCH	2	1	1	0
	APRIL	9	6	3	0
	MAY	43	33	7	3
	JUNE	131	79	40	12
	JULY	195	74	108	13
	AUG	124	54	53	17
	SEPT	53	39	11	3
	OCT	6	5	0	1
	NOV	2	2	0	0
	DEC	2	1	1	0
Autopsy performed	No	189	80	79	30
	Yes	381	215	145	21

Border counties: Cochise, Pima, Santa Cruz and Yuma.

Central Arizona counties: Gila, Graham, La Paz, Maricopa, Pinal, Yavapai.

Northern Arizona counties: Apache, Coconino, Greenlee, Mohave and Navajo.

TABLE 4
DEATHS FROM EXPOSURE TO EXCESSIVE NATURAL HEAT OF THE EIGHTY MIGRANTS TO ARIZONA IN 2002:
CASE SUMMARIES

Case Number	Place of injury as entered on the death certificate¹	City of death	County of death	Condition causing death as entered on the death certificate²	Underlying cause of death (ICD-10 code)³	Month of death
